

ABSTRACT

A medical device and methods of using the medical device to hold a percutaneous endoscopic gastrostomy (PEG) tube. The medical device includes a front side and a back side. The front side includes a left section, a middle section, and a right section. The left section and the right section each include a refastenable material. The back side includes an adhesive section and a non-adhesive section. The adhesive section adheres the device to the skin of a recipient. A PEG tube placed in the middle section is secured within the device by applying pressure to the non-adhesive section until the refastenable material of the left and right sections engage. Conversely, the tube may be removed without affecting the adhesion of the device to the recipient or the integrity of the tube by disengaging the left and right sections of the device.
